The Silicon Electron Multiplier

Thursday, March 16, 2023 2:25 PM (20 minutes)

Silicon sensors for the future generation of collider physics experiments will require high performances on spatial ($< 10 \mu\text{m}$) and time resolution (20-50 ps) with a radiation tolerance up to fluences of 10^{17}n_{eq} . To meet these challenges, a new silicon sensor architecture has been proposed, enabling internal gain without relying on doping, the Silicon Electron Multiplier (SiEM). The SiEM incorporates a set of metallic electrodes within the silicon substrate which are used to create a high electric field region that provides charge multiplication. Simulations of SiEM configurations with TCAD and Garfield++ show a promising performance with a gain exceeding 10. Metal assisted chemical etching is a process shown to be compatible with the desired geometry, and is used to make a demonstrator. Results from a production comprising pillars with a radius of 500nm and a height of up to $8 \mu\text{m}$ on a hexagonal grid with a $1.5 \mu\text{m}$ pitch will be presented along with key results from the simulations.
