Quick Update

- 8 hour study over the range [50,198] MeV conducted in last update was bugged
 - parameter information was lost in the storing process for best fits
 - fixed this bug
- Conducted a 24 hour study over the range [50, 198] MeV
 - 10 functions with values $> 1e-2$
 - modified previous 1d histo plotter
- Conducted round two fitting procedure
 - Took parameters and functions from ^
 - added functions that had performed well in previous round two
- New Display Tool
 - that plots each set of fits for a given function

Last Update: 8 Hour Study - [50, 198] MeV

- 11 functions with pvalue $> 10^{-2}$
- mean pvalue = .003

Top 20 performing functions

1D Pvalue Distribution

24 Hour Study on range [50, 198] MeV

Variance Technique:

Select starting parameters from gaussian with width that is 1% of starting parameter value and change width by an additional 0.5% of mean for every 100 fits without finding better pvalue.

- Improved on pvalue for many functions found in the 8 hour study
- Stored all parameters for each of the best fits to be used in “Round 2 Fitting”
- Fixed 8 hr study bug and rewrote display scripts to reflect proper data format

24 Hour Study on range [50, 198] MeV

- 10 functions with pval > 1e-2
- Unclear if change in variance helped. 1 less function, but better top 10 fits.

new display script modified from
Cam's initial histo plotter

Top 20 performing
functions

Round 2 Fitting Recap

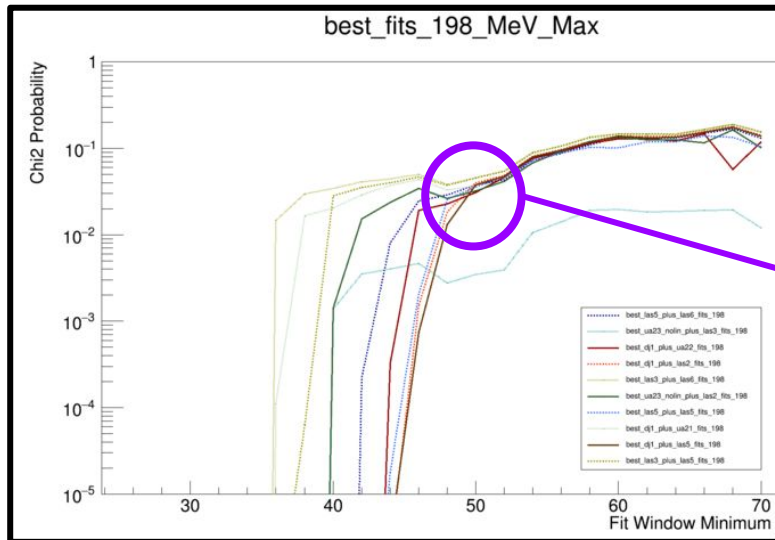

Tested method of using parameters found for las3_plus_1 as the exact seeds used in fitting each window range.

Round 2 Fitting Study Procedure

Fit each function to the IMD over multiple ranges of WinMin/WinMax using stored parameters as a starting place.

- Did not use 8 hr study results due to strings being cut off in previous storing process.
- WinMin Range: $[35, 54]$ MeV 1 MeV step size
- WinMax Range: $[180, 220]$ MeV 10 MeV step size

Previous R2 Study also had selection of well performing functions over the range $[50, 198]$ MeV. Used these parameters if function's fit was better than performance during 24 hr study.

Round 2 Fitting Results

14 Total Functions Found

New Display Tool

Modified previous tool `merge_fits.py` to make `func_merge_fits.py`

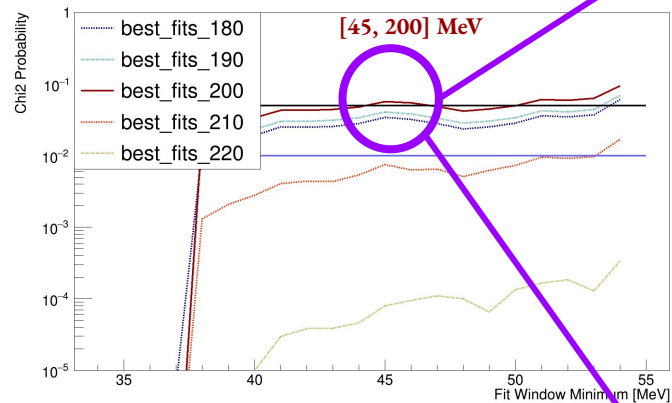

- takes each winmax fixed plot for each function and plots them over the same range of win mins.

Terminal Input: `python3 func_merge_fits.py -n 35 55 1 -x 180 230 10 -B 1`

Notable Fit from Study

best_fits_ua23_nolin_plus_las3

- Next step is to transition away from filtering / finding functions
 - Would like to push through single function through existing fitting infrastructure and see how a result might compare to what Matt/Cam have
 - then will generalize for a set of n functions to compare against and determine bias'

-Interesting parameter observation

Interesting parameter observation

shows that the error function's first parameter has a best region

accidentally ran the 1D distribution script on the first fitting parameter, this displays the distribution of this first parameter value for all functions
