# The BEST Search for Vector-Like Quarks

Samantha Abbott (She/Her) US LHC Users Association Annual Meeting 2024 Stanford, CA

Dec 18, 2024

## Quirky Quarks: Vector-Like Quarks (VLQs)

- Search for new physics: <u>Vector-Like Quarks</u>(VLQs)
  - Commonly predicted by SM extensions
    - e.g. Composite & Little Higgs models
  - ► Top-like (**T**) and bottom-like (**B**)
  - Non-chiral -> vector-like
  - Very massive (>1 TeV)
- We study pair-produced VLQs
  - ► Final State is **diverse** and **boosted**:
    - Fully hadronic

Samantha Abbott

- ► 4 high p<sub>T</sub> AK8 jets
- ▶ W, Z, Higgs, t, b

# Momentum Brings Us Closer

tum Decays

Subjets

AK8 Jet

### Heavy Particles -> Light Decays -> High Momentum Decays

- VLQ mass is on the TeV scale
- ► W, Z, Higgs, t, b are on the **GeV** scale
- AK8 Jets contain several constituents
  - ► These 'daughters' are
    - boosted (high momentum)
    - highly collimated

top quark decay in laboratory frame

## The BEST Method

### The **Boosted Event Shape Tagger (BEST)** steps:

- Boost AK8 jet into different rest frames
- Calculate **BES** variables in each frame
  - Include some frame invariant variables
- Feed vars into simple Neural Net
- Classify!
  - Multi-Object classifier: W, Z, Higgs, top, bottom, QCD
  - Generalized

### Perfect for our all-hadronic search for VLQs!

### 21 Neural Network: The BEST Artificial Brain

UCDAVIS

BES vars

### For each **pT bin**:

- Identify process with the least events
- For the other 5 processes, begin randomly dropping events
  - Continue until they match the process with the least events
- Now, the pT distribution for all 6 processes will have **identical shape**

### 23 Zagging Behavior pT Dependence

### 7.2 Statistical Methods

This search uses a binned likelihood to test for the presence of any discrepancy from the predicted background. A shape-based analysis is performed on the  $H_T$  distributions in all 120 signal regions. Then, these orthogonal regions are statistically combined together and exclusion limits are placed at 95% confidence.

In this analysis, the exclusions limits are set with the CLS method in the Higgs Combine tool. As the analysis evolves there will be comparisons between the CLS results and Bayesian results in order to check the health of the statistical methods. The starting point is to construct a binned likelihood function. This is done using a Poisson likelihood defined as

$$L(d|r,\vec{\theta}) = \prod_{i=1}^{N} \frac{f_i^{d_i} e^{-f_i}}{d_i!}$$
(19)

Where  $f_i$  is the model prediction in bin *i*, and  $d_i$  is the data observed in bin *i*.  $f_i$  is actually  $f(r, \vec{\theta})$  where *r* is the parameter of interest and  $\vec{\theta}$  are the nuisance parameters of the model [26].

### **BEST Confusion Matrix**

Figure 6: A Confusion Matrix for BEST using 2018 Monte Carlo Simulated data. The x-axis is the classification predicted by BEST, and the y-axis is the truth\* label (the actual simulated jet). Along the diagonal are the correct identification rates, and off diagonal entries are mis-identification rates. Each horizontal row is normalized individually, by the total number of truth jets for that category. So, the horizontal rows will sum to 1, but the vertical columns will not.

BEST is performs well at categorizing *H* and *t* jets (with respect to the other categories). BEST shows confusion when trying to discriminate between *W* vs. *Z* jets, but is fairly good at categorizing a jet as *W* or *Z* (with respect to the other categories). Similarly, BEST confuses *b* vs. *QCD* jets, which makes it difficult to separate *b* jets from background.

### BEST: Fraction of Truth Jets Tagged as Higgs Jets by $p_{\tau}$ for 2018

**Figure 7:** Fraction of truth jets tagged as Higgs jets as a function of AK8 Jet  $p_T$ . Notably, the BEST tagging rates are flat in  $p_T$ , which is by design. BEST correctly classifies a truth level Higgs jet ~75% of the time.

This corresponds to the **Predicted Label: Higgs** vertical line of entries on the Confusion Matrix. Each **True Particle** line here matches the corresponding **True Label** box on that **Higgs** vertical line.

### BEST: Percentage of Truth Level Bottom Jets Classified as X by $p_{\tau}$ for 2018 <sup>29</sup>

**Figure 8:** Each BEST category's classification rate for truth level bottom jets, by AK8 Jet  $p_{T}$ . Note that b-tagging degrades at high  $p_{T}$ . This illustrates some of BEST's confusion between b jets and QCD jets.

This corresponds to the **True Label: Bottom** horizontal line of entries on the Confusion Matrix. Each **Classified As** line here matches the corresponding **Predicted Label** box on that **Bottom** horizontal line.

BEST: Fraction of Truth Jets Tagged as QCD Jets by SoftDrop\* Mass for 2018

**Figure 10:** Each BEST category's classification rate for truth level QCD jets, by AK8 Jet SoftDrop Mass. The QCD lines in both plots are identical. The above plot helps explain the dip in jets tagged as QCD near the W and Z mass.

**Figure 9:** Fraction of truth jets tagged as QCD jets as a function of AK8 Jet SoftDrop Mass. BEST is *not* blind to mass like it is to  $p_T$ , so these rates are not flat. The dip in the plot near 75 GeV is due to most jets near that mass being categorized as *W* or *Z* jets, across all categories.

This corresponds to the **Predicted Label: QCD** vertical line of entries on the Confusion Matrix. Each **True Particle** line here matches the corresponding **True Label** box on that **QCD** vertical line.

BEST: Percentage of Truth Level Top Jets Classified as X by Soft-Drop Mass for 2018

**Figure 11:** Each BEST category's classification rate for truth level top jets, by AK8 Jet Soft-Drop Mass. The higher the top jet's Soft-Drop Mass, the better BEST is at classifying it. BEST shows confusion when Soft-Drop mass is near another category's rest mass, as seen in the peaks in the misclassification rates for the top quark.

This corresponds to the **True Label: Top** horizontal line of entries on the Confusion Matrix. Each **Classified As** line here matches the corresponding **Predicted Label** box on that **Top** horizontal line.

### 32 Exclusively the BEST

- Mass exclusion limits
- Improved from previous analysis!
  - More data, improved Tagger

- Have not unblinded!
  - This plot is a measurement of our sensitivity

Compare to world's best:

- m<sub>TPrime</sub> > ~1440 GeV
  - Full Run 2 (all years)
  - 1:1:1 Branching Ratio
  - **Leptonic Final States**
