We need simulations of the interaction point to answer some questions

- 💥 what “luminosities” can we achieve depending on the beam parameters?
- ✨ what wakefield collider would be “best” and in what sense?
- 🔬 what discoveries can we make?

GUINEA-PIG

CAIN

<https://gitlab.cern.ch/clic-software/guinea-pig> <https://github.com/slaclab/CAIN>

many beam-beam effects:

disruption 💔, photon emission 🔦, pair creation 🐱🐱, scattering ⚫, hadron photoproduction 💪,

...

→ luminosity??? backgrounds???

nominal beams 😍

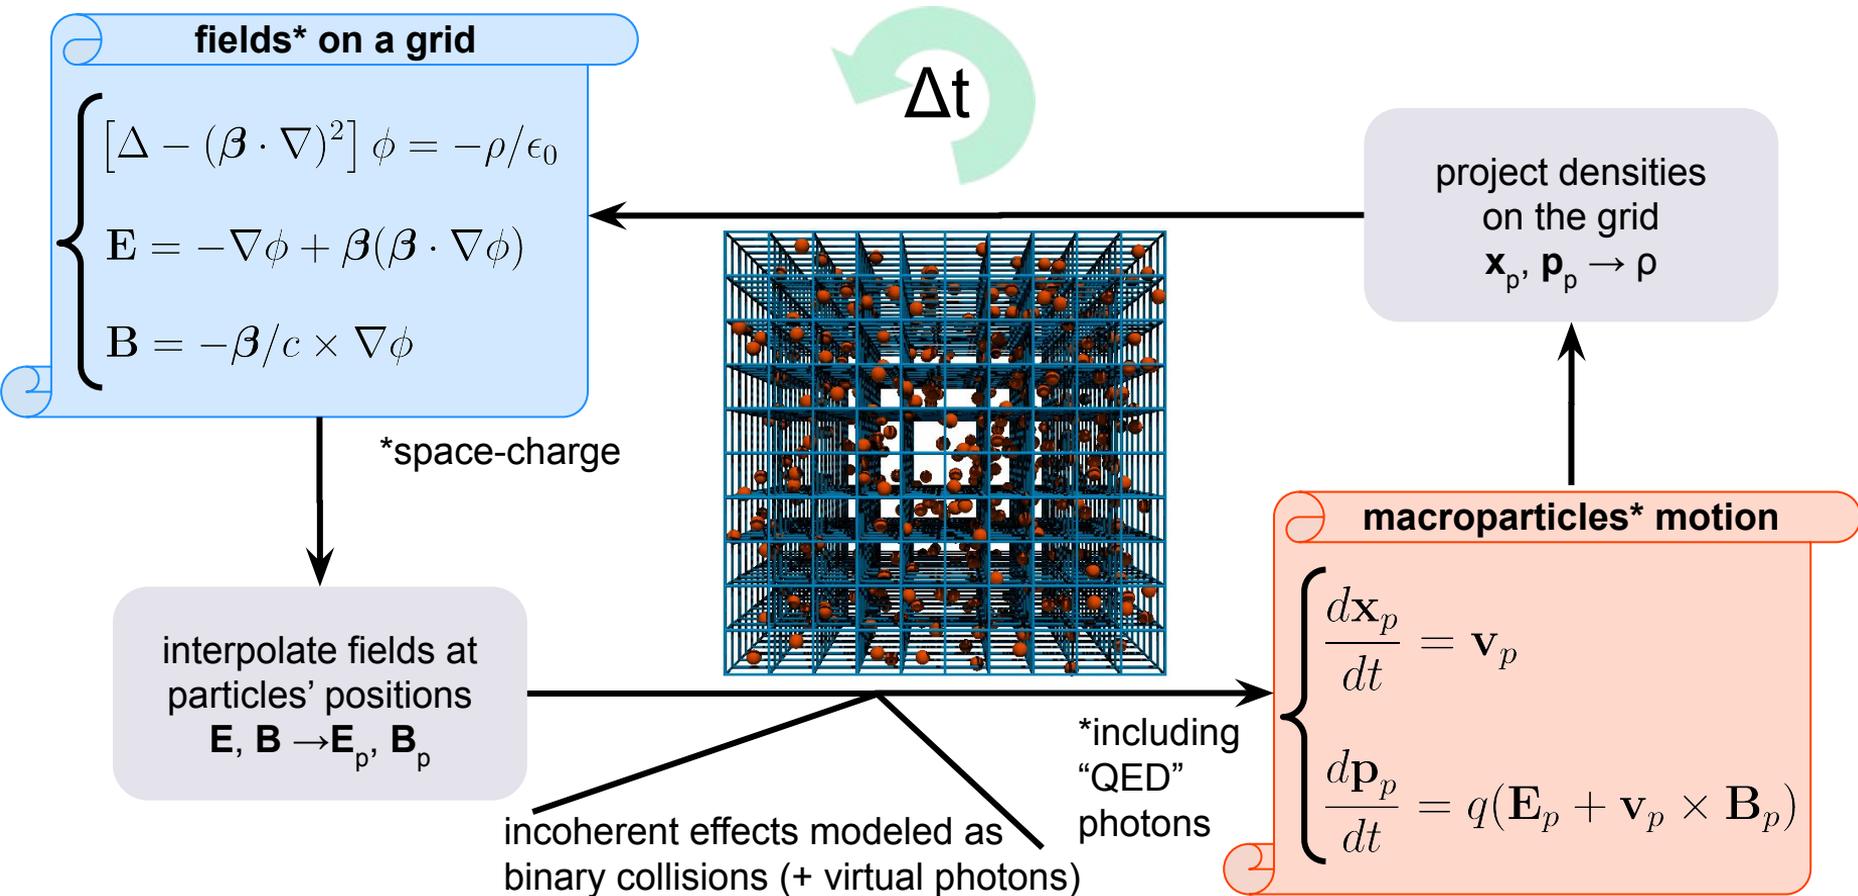

disrupted beams 😱

electrons

positrons

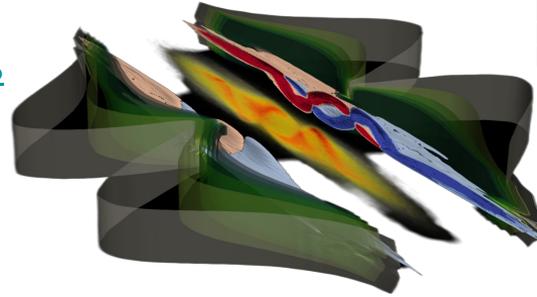

Particle-In-Cell + Monte Carlo simulations are the standard modeling tools

WarpX is a particle-in-cell code that can simulate beam-beam effects

<https://ecp-warpX.github.io>

<https://warpX.readthedocs.io>

open-source
OS portable: Linux, MacOS, Windows,
GPU portable: NVIDIA, AMD, Intel
multi-platform: multi-CPU/GPUs, laptops → clusters
flexible:

- different geometries: 1D, 2D, RZ, 3D
- many algorithms
- many diagnostics
- electromagnetic, electrostatic in beam frame
- QED modules

international, cross-disciplinary & ACTIVE community!
(WELL) DOCUMENTED!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!

 **HIGH PERFORMANCE SOFTWARE FOUNDATION**

Beam-beam collision

This example shows how to simulate the collision between two ultra-relativistic particle beams. This is representative of what happens at the interaction point of a linear collider. We consider a right-propagating electron bunch colliding against a left-propagating positron bunch.

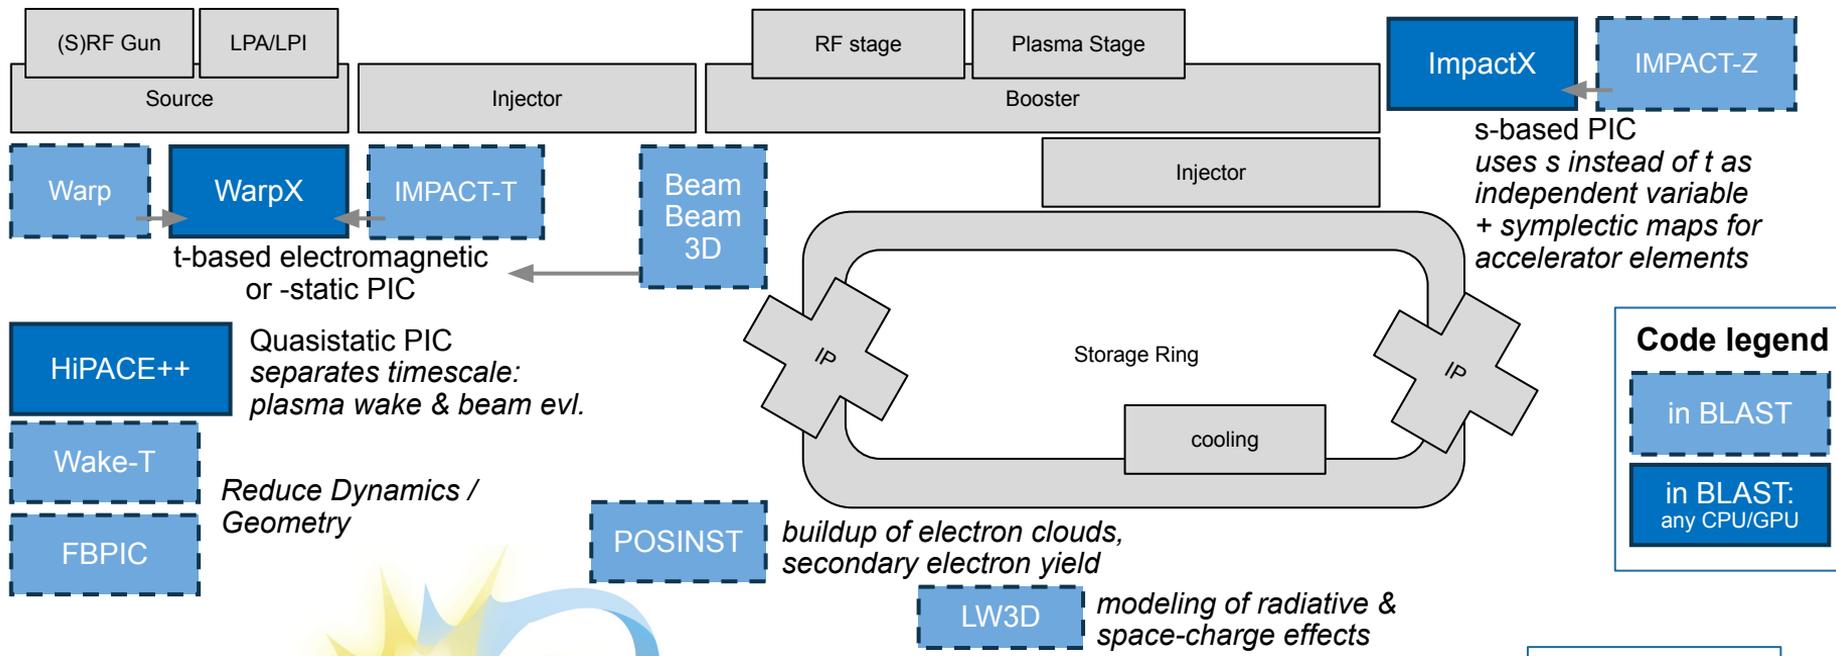

We turn on the Quantum Synchrotron QED module for photon emission (also known as beamstrahlung in the collider community) and the Breit-Wheeler QED module for the generation of electron-positron pairs (also known as coherent pair generation in the collider community).

To solve for the electromagnetic field we use the nodal version of the electrostatic relativistic solver. This solver computes the average velocity of each species, and solves the corresponding relativistic Poisson equation (see the WarpX documentation for `warpX.dg_electrostatic = relativistic` for more detail). This solver accurately reproduced the subtle cancellation that occur for some component of the $\mathbf{E} \times \mathbf{v} \times \mathbf{B}$ terms which are crucial in simulations of relativistic particles.

This example is based on the following paper Yakimenko et al. [9].

Excellent agreement between WarpX and other codes with spherical nanobeams

- $E_{COM} = 250$ GeV
- $N = 8.7 \cdot 10^8$
- spherical beams: $\sigma_z = \sigma_x = \sigma_y = 10$ nm
- zero emittance
- low disruption $D = 0.001$
- max quantum parameter $\chi = Y \sim 1700$

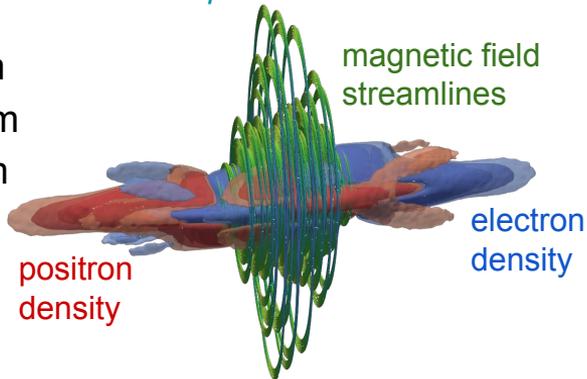

Yakimenko et al. PRL 2019

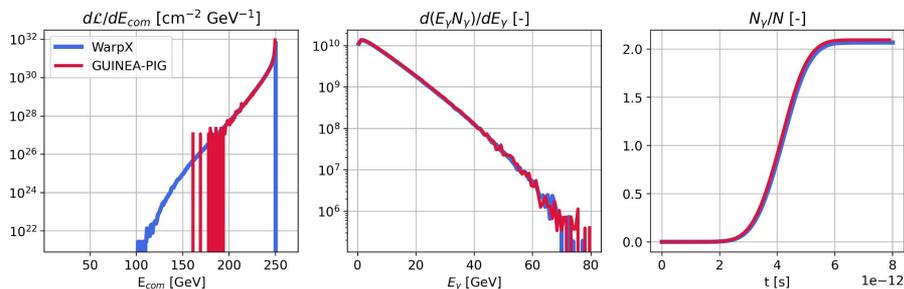

Excellent agreement between WarpX and GUINEA-PIG with flat ILC beams

*The International Linear Collider:
Report to Snowmass 2021*

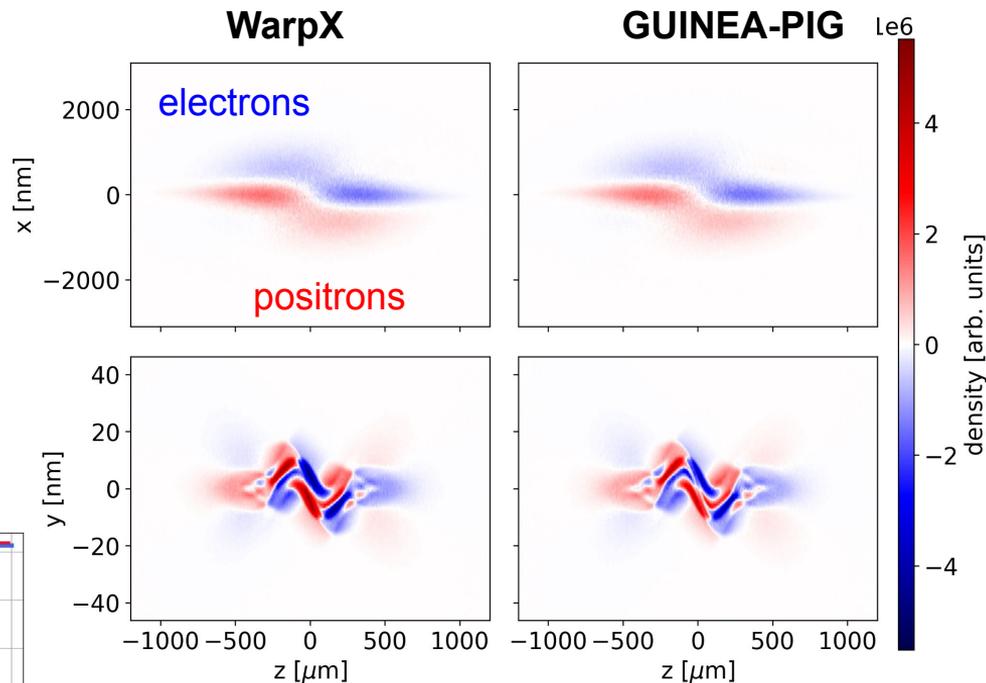

- $E_{\text{COM}} = 250 \text{ GeV}$
- $N = 2 \times 10^{10}$
- $\sigma_z = 300 \text{ } \mu\text{m}$
- $\sigma_x^* = 516 \text{ nm}$
- $\sigma_y^* = 7.7 \text{ nm}$
- $\epsilon_x = 5 \text{ } \mu\text{m}$
- $\epsilon_y = 35 \text{ nm}$

- flat beams
- significant disruption $D_x = 0.30$, $D_y = 24.39$
- max quantum parameter $\chi = Y \sim 0.3$

snapshot of the beams' **density integrated along the missing coordinate** during collision

offsets along x and y $\sim \sigma_{x,y}/10$ to induce the kink instability and mitigate stochastic discrepancies

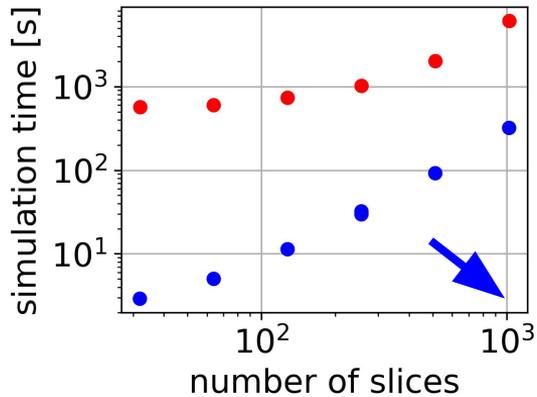

WarpX can be faster and/or go to higher resolution and statistics

First simulations with wakefield lepton beams at 10 TeV – preliminary!

⚠ SEVERAL CAVEATS EXIST ⚠

luminosity spectra

$E_{\text{COM}} = 10 \text{ TeV} \mid N = 1.2 \cdot 10^9 \mid \sigma_z = 8.5 \text{ } \mu\text{m}$

e^+e^- vs. e^-e^-

round: $\sigma_x^* = 1.55 \text{ nm} \mid D = 1.22 \mid \chi = 970$

flat: $\sigma_x^* = 6 \text{ nm} \mid \sigma_y^* = 0.4 \text{ nm} \mid D_x = 0.15 \mid D_y = 2.3 \mid \chi = 470$

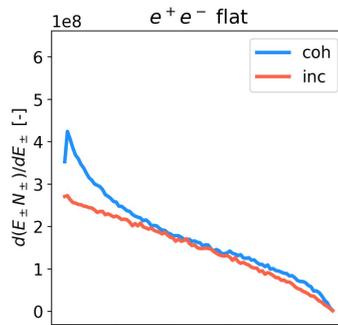

The caveats

Simplifications

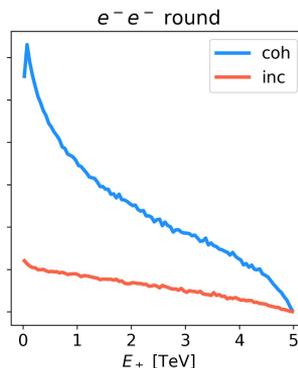

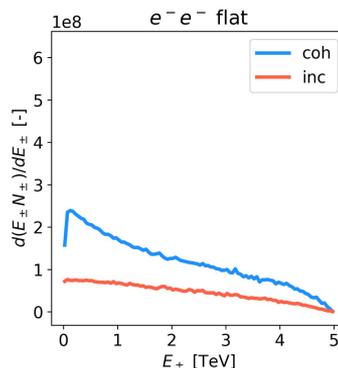

- local constant field approximation (LCFA)
- collinear emission of photons
- only coherent processes (beamstrahlung & nonlinear Breit-Wheeler)

Physics open questions

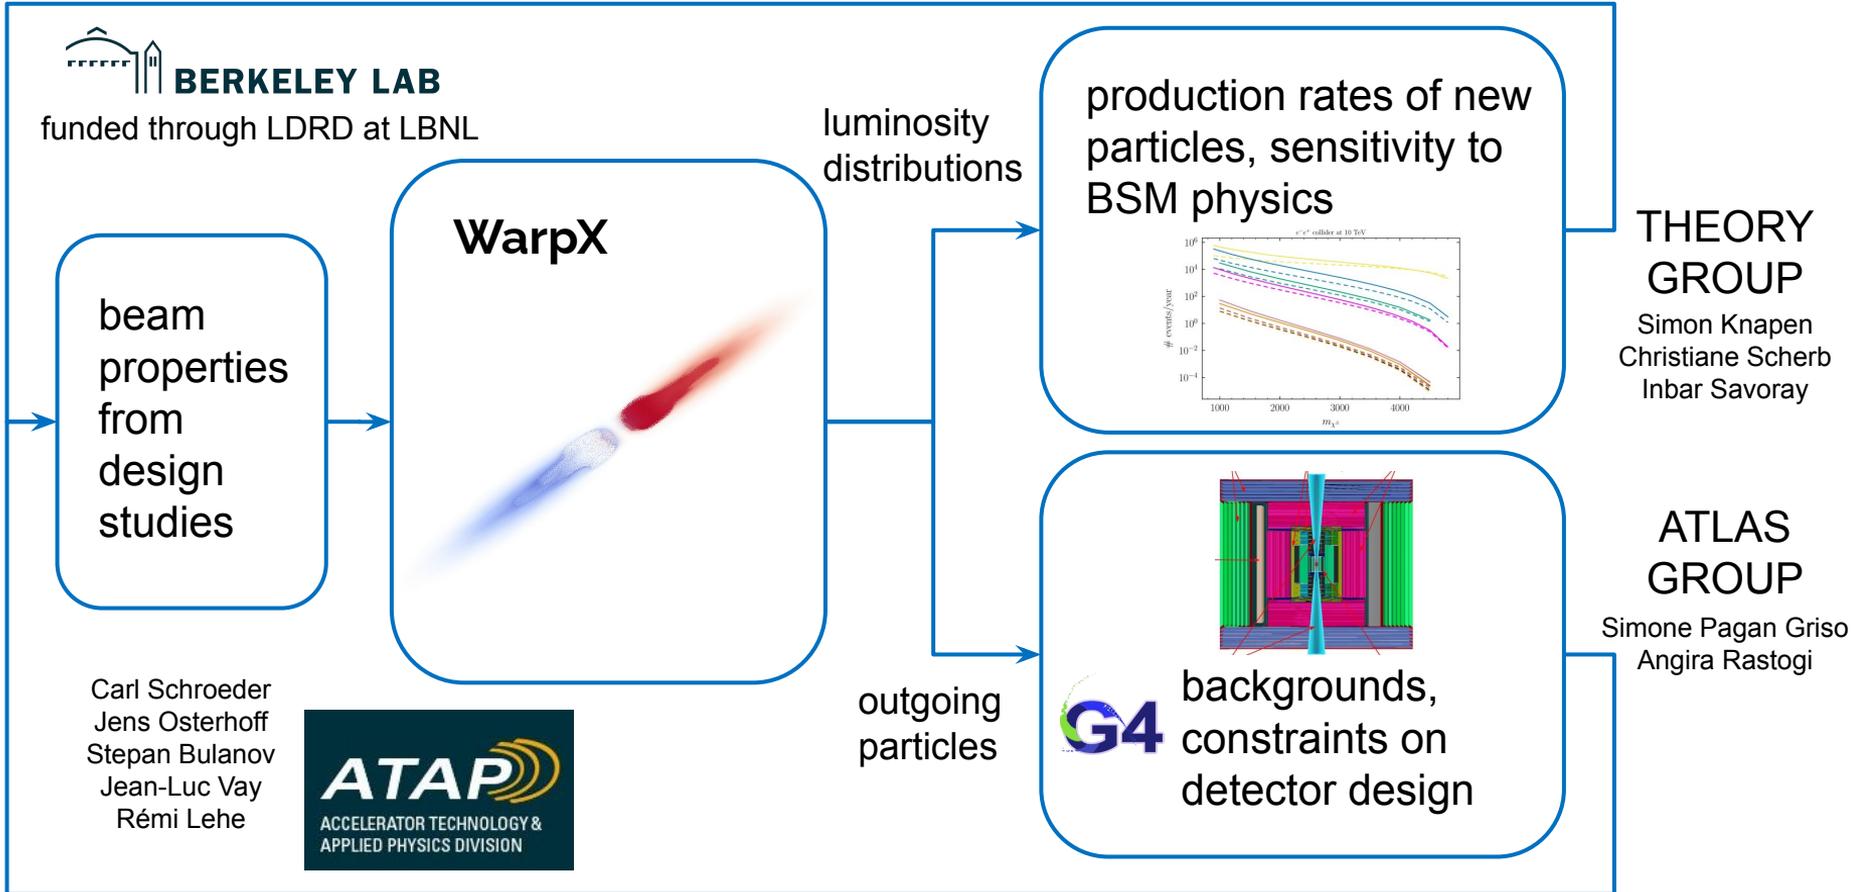

- transition from incoherent to coherent photon emission
- transition from incoherent to coherent pair generation
- emission rates at very high quantum parameters
- validity of LCFA
- circular colliders: couple with other codes
- other processes for muon colliders?
- ...

this simulation didn't finish, my bad 😞

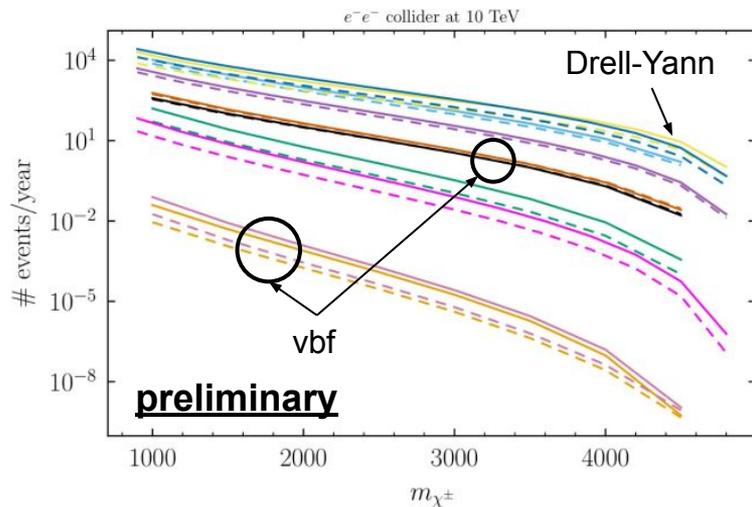

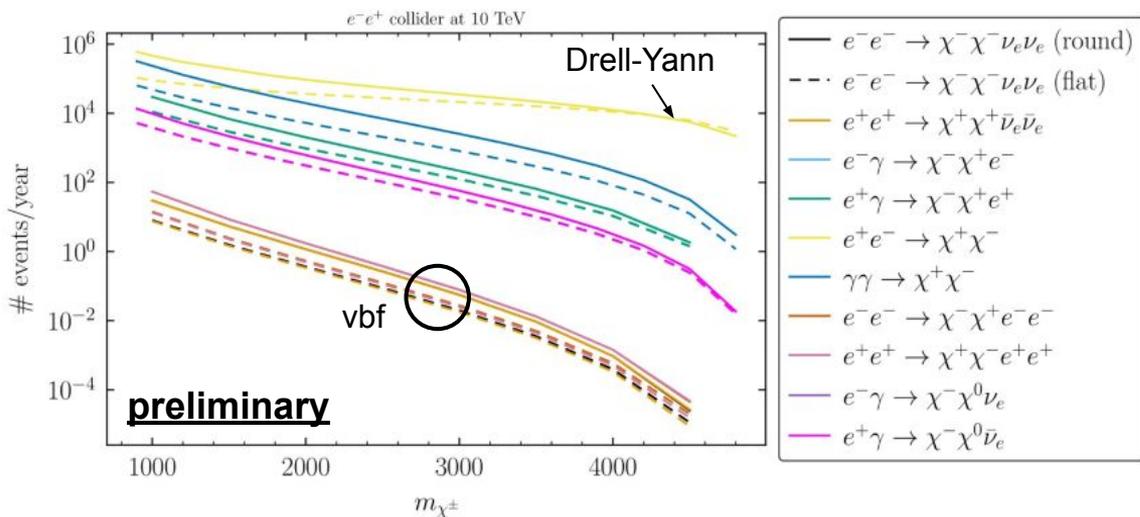

We are setting up a framework that includes accelerator-physics-detector

From the luminosity distributions we get the production rate of exotic particles

searching wino-like chargino χ^+ as visible charged partner to χ^0 (dark matter candidate)

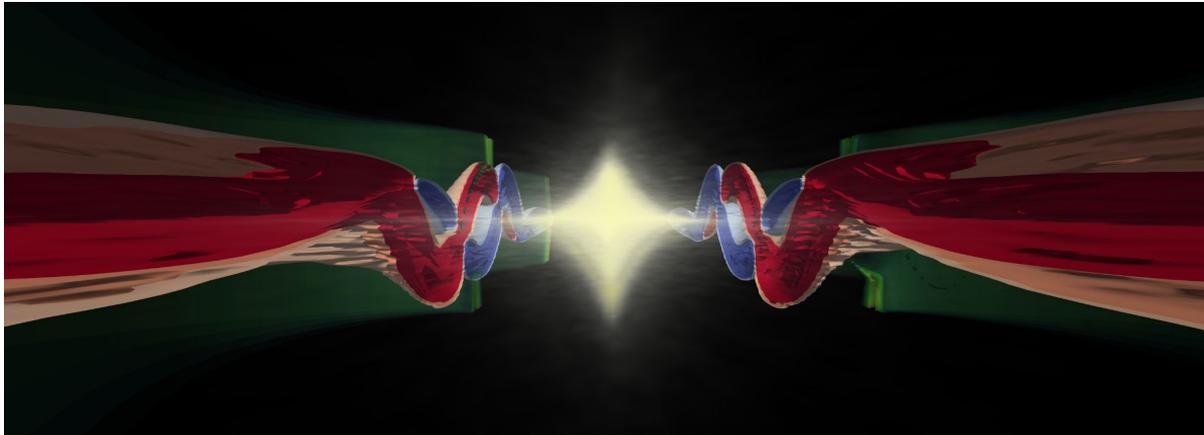

- use MadGraph to generate events for chargino production
- to include luminosity spectra need to run over grid of center of mass energies and fold with luminosity spectrum
- repeat for multiple chargino masses
- (implement decays by hand)

Conclusions

main takeaways 🏁 and next steps ▶▶

- 🔄 we are continuing to develop WarpX as a next-gen code for IP simulations
- 🎯 WarpX agrees well with and is much faster than GUINEA-PIG
- 🚧 we are developing a broader simulation framework to support the design of future colliders in a cross-disciplinary team
- 🤔 we started and will continue addressing the caveats!

Thank you for
your time! 🙏
